Vehicular Ad-Hoc Networks(VANETs)

Applications

- Safety critical applications
- Convenience applications

● Traffic management and control systems

● Parking availability

- Comfort applications

● Entertainment applications

● Web browsing services

Vehicular Ad-Hoc Networks(VANETs)

• Applications

- 1 Safety critical applications
- 2 **Convenience applications**
 - Traffic management and coordination application
 - Parking availability
- 3 **Comfort applications**
 - Audio and video streaming
 - Web-browsing, Email

Vehicular Ad-Hoc Networks(VANETs)

• Applications

① Safety critical applications

② **Convenience applications**

- Traffic management and coordination application
- Parking availability

③ **Comfort applications**

- Audio and video streaming
- Web-browsing, Email

VANETs: advantages and disadvantages

- Advantages

- 1 No energy or computational power limit
- 2 **Positioning information**
- 3 Highly predictable mobility

- Disadvantages

- 1 Frequent network topology change due to vehicle mobility
- 2 **Fleeting** communication between AP and vehicles
- 3 **Intermittent** communication between AP and vehicles

Objectives

- Propose a scheme to efficiently download the contents from the AP for the vehicles in VANETs
 - As much as possible
 - As quick as possible

Assumptions

- A group of vehicles interested in one content is formed.
- A group header is selected among the vehicles to send initial request for the content.
- The sequences of the vehicles are sent to the AP by the group header.
- All nodes work in overhear mode.

Main idea — cooperative downloading

- Consecutive downloading of the same content.
- Smooth handover of the downloading from one vehicle to another vehicle.

Demonstration(1)

Demonstration(2)

Demonstration(3)

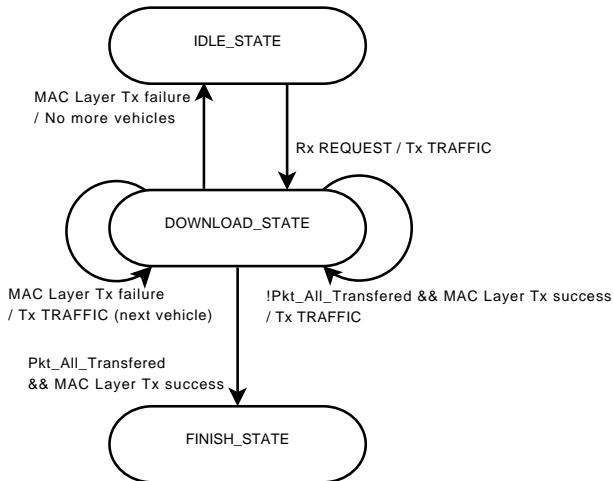

Demonstration(4)

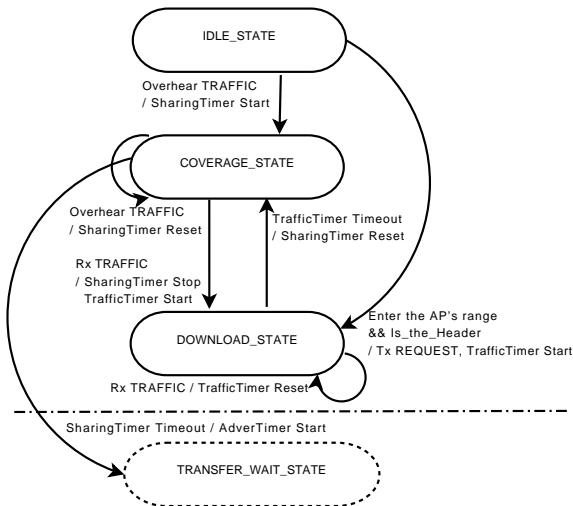

Demonstration(5)

AP state flow

Vehicle state flow

Main idea — V2V sharing

- 1 The sender vehicle transmits one-hop broadcast ADVER message to tell other vehicles the packets they have.
- 2 The other vehicles ask for the missing contents from the sender by sending CTS messages.
- 3 The sender uses positioning informations to select message receiver(the farthest from the sender).

Demonstration(1)

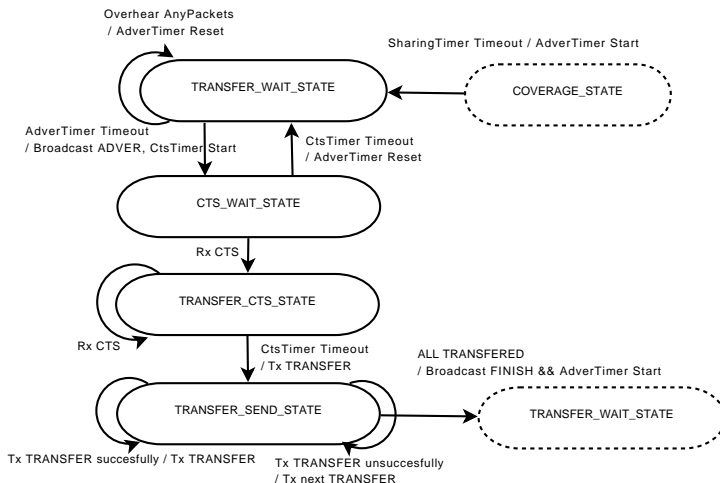

Demonstration(2)

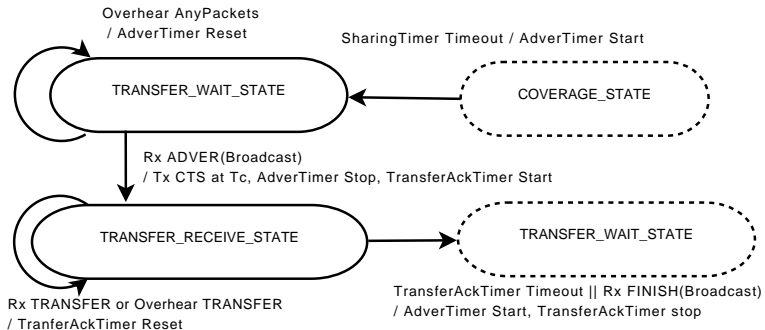

Demonstration(3)

Vehicle send state flow

Vehicle receive state flow

Implementation

- The scheme is implemented on the Network Simulator 2(NS2)
- Application layer
 - *VCDClient* - vehicle
 - *VCDServer* - AP
 - *GroupManager* - group management protocols
 - *InputParameter* - input tunable simulation parameters
- Lower layer
 - Overhearing of unicast message
 - Cross layer ACK notification
 - Modifications of AODV protocol

Default parameters

- Unlimited file size
- Mobility pattern
 - Constant speed at 10m/s
 - 50 meters away from each other

An example

- With respect to one vehicle case
 - Number of received packets per vehicle is 16.70% higher.
 - The group throughput increases by 54.1%.

Number of received packets per vehicle

- Number of received packets per each vehicle increases linearly as vehicles in the group increases.

Time spent in sharing phase

- The time increases as the group size grows.
- The variance is higher when there are more vehicles in the group.

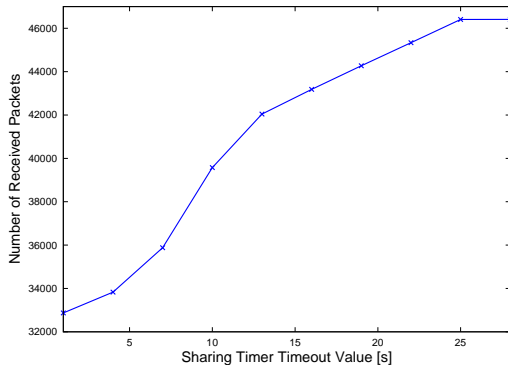

Throughput per vehicle

- The throughput per vehicle decreases as the group size increases because more time is spent in sharing phase and more collisions occur.

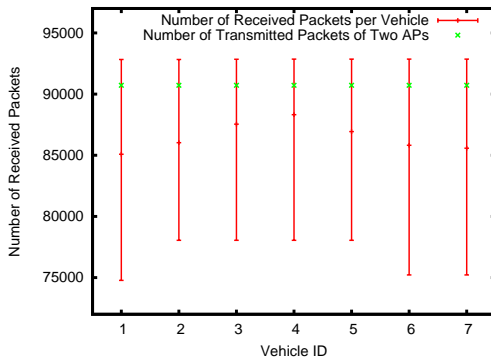

Number of received packets per vehicle

- The number of received packets increases as the timeout value increases.
- It reaches saturation point at time 25.

Throughput

- The packet receipt status is different because there is not enough time in between two APs to share the contents.

Conclusion and future works

- Conclusion

In order to efficiently download contents for nodes in VANETs, a scheme, composed of cooperative downloading and V2V sharing phases, is proposed, implemented and evaluated.

- Future work

- 1 The group management protocol needs to be added.
- 2 A more realistic mobility pattern model should be used to evaluate the performance.
